

# UNDERSTANDING INFORMATION LEAKAGE IN E-MAIL HEADERS

Joshua Clark

Fourth Year Project Report for the Final Honour School of Computer Science

May 2016

# **Abstract**

After extensive public education, fewer people are now clicking on links in e-mails that are disguised as phishing attacks, though the threat still remains, and considerable amounts of work has gone into exploring the demographics most likely to be targeted. As the number of technically literate people grows, this sort of attack is increasingly unlikely to be successful. Therefore, malicious entities are more likely to attempt to attack people based on the information leaked in their emails, and more specifically, the header, which most people are less likely to have some degree of control over.

The risks are not just limited to individual users, and at a corporate level, the risks posed by leaking information through e-mails could be even greater: e-mail headers can reveal the internal network structure of a company's computer systems as well as the different pieces of software that are running inside the system. Extracting the social information could be of great value for executing a phishing attack, however, there is also value in determining the specific weaknesses in a system. This can be aided through the use of vulnerability databases.

This report discusses the existing research into the information leaked by e-mail headers and presents a tool to extract such information. The tool's design and implementation is discussed, followed by the results of its testing.

# Acknowledgements

I want to thank my supervisor, Dr Jason R.C. Nurse for his assistance throughout the year; my tutor, Professor Peter Jeavons, for his unfailing help and support throughout my time at Oxford. I would like to thank the residents and chaplains of the Oxford University Catholic Chaplaincy. Finally, I would like to acknowledge the support from my family and partner, Agata Borkowska, for encouraging me.

# 1. Introduction

#### 1.1. Motivation

E-mail systems are now so integrated into our modern lives that we struggle to cope without them. E-mails ubiquity is also one of its largest weaknesses, a fact recognised very early on. The first spam email was sent in 1978, as documented by Templeton n.d. After spam came phishing, first described by Felix and Hauck 1987, with the first-real world use being against the customers of America Online, an ISP. However, this still relies on the targets providing their data for malicious purposes. One of the first e-mail viruses to spread was the Happy99 virus, which, other than propagating itself, had no other effect on infected systems. Later viruses would target credit-card and banking information. However, all of these techniques rely on the malicious email being received and its contents being opened. There are fewer instances recorded, however, of the information flow being sent the other way. A more subtle attack will focus on the information being sent from a legitimate user to an attacker. It is easy enough for an individual to read an e-mail header and identify interesting elements, however, on a large scale, this quickly becomes more difficult.

# 1.2. Aims and Objectives

This project aims to support a better understanding of the data that may leaked when e-mails are sent, both from a personal perspective, as well as the corporate data that is leaked concern network configurations and software installations.

To support this, I will develop a tool that can be used as described above to automatically extract information from e-mail headers and analyse its results to display the personal information contained within an e-mail's header, as well as information about the software configurations that may be found on a user's computer, or the servers used to send their e-mail.

The tool's objectives will be to parse, analyse and visualise the contents of any e-mail header that it is given. The parsing process should correctly and efficiently convert the plaintext of an e-mail header into an abstract representation. In the analysis section, the representation of the header should be searched to find information out about the sender, their software and device, and information for any servers that the e-mail message passes through. Finally, the visualisation produced should clearly show the information that is available about the sender of an e-mail and the path the e-mail took in order to arrive at its final destination.

#### 1.3. Structure

Chapter 2 begins by discussing the existing research on the subject as well as existing publicly-available tools to analyse headers. I then use these as a basis to discuss features

that would be expected to appear in a header analyser looking for leaked information and vulnerabilities.

The specification and design of a program to support the understanding of the information leaked in e-mail headers is discussed in Chapter 3. The implementation's high-level structure and details will be discussed in Chapter 4, and algorithms presented in pseudo-code where necessary. A full listing will be presented at the end of this document in an appendix. The results of the analysis of the headers will be discussed in Chapter 5, beginning with the methodology used, and presenting a number of results, finishing with conclusions and areas of further improvement.

# 2. Literature Review

In this chapter, we will discuss the nature of existing threats to data, and the ongoing research in this area. We will then consider the specific threats posed by e-mail.

## 2.1. General Data Leakage

The importance of data leakage is gaining more importance as the amount of information stored about entities increases, and the risks are being considered more carefully. From the obvious ramifications for businesses discussed in Papadimitriou and Garcia-Molina 2011: the loss of trust and legal action resulting from the discovery of leaking data, to the more personal issues discussed in Irani et al. 2011: the possibility of using the discovered data to discover passwords or to physically identify them. 53% of Americans can be uniquely identified by their birth date, gender and location (city/town), with the number jumping 87% when using birth date, gender and zip code.

#### 2.1.1. Personal Data Leakage

From a personal perspective, there are a number of risks. There are a significant number of social networks available, with an estimated 1.65 billion monthly active users, with a significantly higher proportion used in developed countries. Irani et al. 2011 showed the rate at which the information gathered from social networks can be used to uniquely identify an individual.

Irani et al. 2011 defines the aggregate normalised attribute leakage as

$$\Psi(F_{a},P) = \frac{\sum_{f_{a} \in F_{a}} \phi\left(f_{a},P\right)}{|F_{a}|} \text{ where } \phi\left(f_{a},P\right) = [f_{a} \in P]$$

for a user's social footprint P, and attributes are referenced as  $f_a$ .

Only 9 sites are required before there is approximately a 0.7 attribute leakage, corresponding to a 70% probability that both a person's hometown and name could be recovered. A similar number of sites can give an aggregate normalised attribute leakage of 1, where it becomes almost certain that an individual may be uniquely identified.

#### 2.1.2. Corporate Data Leakage

When companies receive user data, they often have a legal obligation to ensure that the data is protected and treated as confidential and sensitive. When this trust is broken, there are often severe consequences, both from regulators and consumers moving their business to competitors.

In addition to ensuring that human procedures are present to ensure the integrity and confidentiality of data, it is also necessary to ensure that robust technical measures are in place to prevent data breaches. The Identity Theft Resource Center 2016 lists a total of 12

million data records from 399 breaches as having been illegitimately accessed in 2016 to date. Two fifths of these data records are connected to government or military data breaches, with a third linked to medical and healthcare data, and a further fifth connected to business data.

Squicciarini, Sundareswaran, and Lin 2010 considers one way that data may be leaked, despite care being taken to ensure that it is properly encrypted and stored: by failing to protect against the indices for databases being stored insecurely, customer data may be leaked. Order-preserving encryption schemes, as described in Agrawal et al. 2004, is one way of solving this problem, to an extent.

## 2.2. Data Leakage from E-Mails

#### 2.2.1. E-Mail Headers

All e-mails include additional information about the sender and receiver, some of which is used by an e-mail client in order to display more information about the message that is currently being viewed, such as its original sender, reply-to addresses and the time it was sent. Additional fields allow senders to authenticate themselves using public-key methods.

The format of e-mail headers was first defined in RFC 822, and further refined in subsequent RFCs. The standard for e-mails was then formalised precisely in RFC 5322.

#### 2.2.2. Example Header and Pertinent Data

In the example below, and text highlighted with red, like so is information about the receiver. Information about the sender, their hardware or software is highlighted in green, like so; and information gathered about intervening devices is highlighted in blue, like so.

E-Mail Header Fragment 2.1: Sample E-Mail

The particularly interesting portions of the e-mail header include the IP addresses of the various servers the message has travelled through, allowing their approximate location to be determined. Additionally, the information on the protocol being used and the software being run allows for anyone with access to mail headers to find more information about the attacks a device and its software may be vulnerable to.

In Example 2.2, indicates that a server with an internal IP address of 10.25.150.146 in the Pacific Seaboard Timezone received the e-mail using the SMTP protocol.

```
Received: by 10.25.150.146 with SMTP id y140csp543137lfd;
Sat, 6 Feb 2016 08:49:56 -0800 (PST)
```

E-Mail Header Fragment 2.2: E-Mail Server configuration information

In Example 2.3, a number of pieces of information can be extracted: the hostname of the sending device is client-8-32.eduroam.oxuni.org.uk with associated 192.76.8.32 is on the eduroam network, with a local IP address of 10.26.196.156.

```
Received: from [10.26.196.156] (client-8-32.eduroam.oxuni.org.uk [192.76.8.32])

E-Mail Header Fragment 2.3: Information revealed in Received field
```

Further examples from headers that may be particularly interesting include the following examples.

Many Apple iOS devices will include hardware and version names in the X-Mailer field.

X-Mailer: Zimbra 8.6.0\_GA\_1153 (MobileSync - Apple-iPhone7C2/1305.238)
E-Mail Header Fragment 2.4: Apple iPhone version

#### 2.2.3. Existing Research

In Nurse et al. 2015, the idea of using the information available in an email header was mooted, turning the previously standard threat of malware and phishing contained in received e-mails on its head, and instead presenting the threat in outgoing emails, and the personally identifying information (PII) contained therein. Many emails leaked information about employers, e-mail services and applications used, and IP address. Initial examination of a variety of e-mail headers found within my own inbox also revealed a plethora of information, including phone carriers, preferred languages, and system usernames. It is conceivable therefore, that it is possible to automate at least part of this, and present the information that can be extracted, in a white-hat tool to allow people to audit the information that they are revealing. The obvious malicious use-case involves using such information as part of a spear-phishing exercise.

An alternative vulnerability presents itself in the information about systems that may be revealed. Many email clients embed identifying information, and there are multiple databases available to allow specific threats to be identified. This could allow a malicious entity to compromise the security of a target machine, and gain access to the data stored on that machine and available on any connected network devices. Work started in Joshi, Lal, and Finin 2013 discusses the need to aggregate data about vulnerabilities from multiple sources to present a more complete and coherent picture, which is also likely to then contain more accurate data.

Al-zarouni 2004 presents an alternative set of results, describing how an individual can seek to protect themselves against malicious e-mails, using the contents of e-mail headers. Various discrepancies between forged e-mail addresses and legitimate messages are described.

# 2.3. Existing Tools

Several tools already exist online to display the information that is found in e-mail headers. Tools from Microsoft and Google exist to analyse the contents of e-mail headers. These tools clearly display the information displayed in the header, showing the key-value pairs, and the set of servers the message transferred through and the protocols used.

#### 2.3.1. Google

The Google Apps Toolbox features an e-mail header analyser<sup>1</sup>. An example of the output of the utility is found in Figure 1.

One of the most useful features from the Google Apps Toolbox is the information provided about the servers the message travelled through. This tool shows the details of the time taken for each hop, and the protocol used.

#### 2.3.2. Microsoft

The Microsoft Message Header Analyser<sup>2</sup> and showing sample results in Figure 2 is of a similar nature to the Google tool, discussed in Subsection 2.3.1. In addition to the information

<sup>&</sup>lt;sup>1</sup>Found at https://toolbox.googleapps.com/apps/messageheader/

<sup>&</sup>lt;sup>2</sup>Fount at https://testconnectivity.microsoft.com/MHA/Pages/mha.aspx

Figure 1.: Google Apps Toolbox E-mail header output

presented by Google, this tool also produces a set of "Other Headers", highlighting fields that may be of interest. However, little additional context is provided as to their relevance.

#### 2.4. Vulnerabilities

Beware of bugs in the above code; I have only proved it correct, not tried it.

Donald Knuth

Problems in software are nothing new, and seeking to exploit these issues is almost as old. As the security implications behind flawed software became more widely recognised, reducing their impact wherever possible became the next most important step. The MITRE Corporation operates the National Cybersecurity Federally Funded Research and Development Centre, which exists to maintain a database of these vulnerabilities, which are referred to as Common Vulnerabilities and Exposures (CVE).

#### 2.4.1. MITRE CVE Lookup

There are a number of tools to look up CVEs<sup>3</sup> and showing sample results in Figure 3. There are a number of limitations to the results returned by the CVE Mitre tool. Firstly, little context is returned: information about scores, the impact and access information are omitted, for example. Additionally, the process of finding relevant vulnerabilities is further slowed down by the necessity to search for specific terms one at a time. Additionally, automated tools exist at a consumer and enterprise level that will automatically scan a computer or network to detect installed software configurations and show the results.

<sup>&</sup>lt;sup>3</sup>Fount at https://www.cve.mitre.org/find/index.html

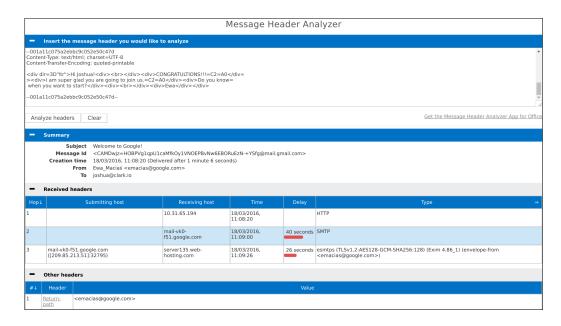

Figure 2.: Microsoft E-mail header output

Figure 3.: CVE Search Results

#### 2.4.2. Norton Vulnerability Protection

For example, the now deprecated Norton Vulnerability Protection tool, as shown in Figure 4<sup>4</sup> lists the programs and the total number of vulnerabilities found, providing more information on each program. This method has the advantage of indicating the specific programs that have vulnerabilities, with the aim of allowing a user to update their vulnerable applications, however it does not allow for more fine-grained information.

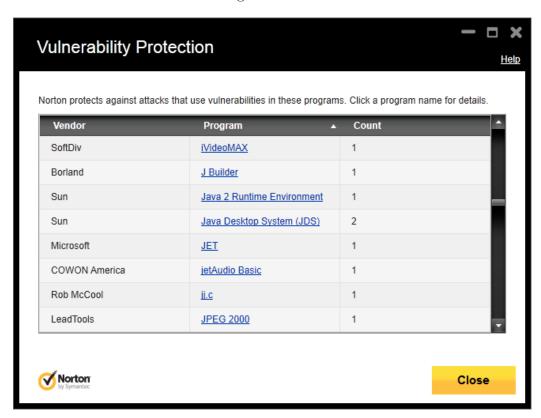

Figure 4.: Norton Vulnerability Protection Results

# 2.5. Summary

There breadth of research available indicates the importance that is placed on maintaining data security, as well as the attempts to track and report on breaches, allowing individuals and companies to track when their data may be exposed. There is also a research available on the data that is willingly disclosed by individuals, and this analyses the risk to individuals that a malicious actor accumulating this data can present.

Less research is available on the nature of the data leaked through e-mails, though it is becoming more common, with information also being provided on ways to protect against malicious or spoofed e-mails, as well as significant amounts of work on spam-detection.

There are a number of specific tools available designed to analyse e-mail headers, however, their main focus is usually on presenting the trace fields, rather than the information that

<sup>&</sup>lt;sup>4</sup>Available at community.norton.com

may be extracted from the rest of the e-mail.

Finally, available tools for analysis of CVEs tend to have divergent aims, with the tool either being aimed at experienced professionals, offering a lot of data, but only if the user is familiar with the system of CVEs, or offering just enough information to allow a system to be kept updated as vulnerabilities are discovered.

# 3. An Approach to Support Understanding of Data Leakage in E-Mail Headers

#### 3.1. Overview

In order to satisfy the aims of this project, and building on the presented objectives, this chapter discusses the requirements of the software intended to analyse e-mails and the design of the program and its specifications.

# 3.2. Program Specification

The software should automatically extract information from e-mail headers and analyse its results to display the personal information contained within an e-mail's header, as well as information about the software configurations that may be found on a user's computer, or the servers used to send their e-mail.

The program would be expected to satisfy the following minimal requirements in order for it to be considered successful:

Accuracy — any information produced by the parser should be reflective of the input e-mail

**Representation** — the produced visualisation should be intuitive to read: each element should be presented separately from the others, and clearly labelled.

**Portability** — the visual output produced by the program should be available to the user in a variety of formats.

**Interactivity** — the program should produce sensible warnings when an e-mail that is not possible to parse has been entered.

# 3.3. Program Overview

The program is split up into three main stages: textual analysis and parsing; header contents analysis, and visualisation, as shown in Figure 5. The relevant data is often stored in a central MainWindow class, rather than passed as a parameter, as the composition would indicate, allowing clear references to be maintained.

The analysis is implemented as a series of stages, firstly, the e-mail header is parsed, to extract important information to a predefined set of Java objects. This is followed by the analysis phase, where the resultant data is passed to a set of analyser modules, each running separately. Finally, this information is presented to the user. After discussing an overview of each module, this chapter presents each of these stages in detail.

Figure 5.: Simplified Control Flow of Application

#### 3.3.1. Parsing

This module receives the plain-text of the e-mail as an input, splitting it into two sections, fields with the "Received" tag, and all other fields. These are then parsed separately. The other fields are easier to parse, as they can be loaded into a hash-map, split by the colon. The trace fields require a more complex parsing strategy, fully described in Section 4.3.1. This information is then extracted to more abstract Java objects, allowing the relevant information to be queried on a device-by-device basis, rather than constantly referring back to the source text.

#### 3.3.2. Analysis

The analysis of the e-mail headers is handled independently by a number of small classes, each running asynchronously. The decision was made to structure the program in such a way that concurrent operation was possible in order to prevent blocking operations from limiting the progress of other operations. This also required care to ensure the separation between the model of the header and the model of the available information was maintained, as no guarantees could be placed on which thread was modifying data.

It is in this part of the program that the automated discovery of vulnerabilities takes place. An example software configuration string is cpe:/a:cloudbees:jenkins:2.2, so it is necessary to attempt to convert found software information. For example, Apple Mail would become apple:mail and a search would be performed over the database for configurations containing that string.

#### 3.3.3. Visualisation

Once the header has been analysed, it is then necessary to present the information that has been found in a useful and informative manner. Firstly, the information about the individual sender, such as their name, organisation, software and usernames, should be presented (where it exists). The information about the servers that the e-mail has passed through should then be detailed, their address, location and software, as well as relevant vulnerabilities.

Once this has been listed, information about the scores of the vulnerabilities for each piece of found software, and a listing of the available vulnerabilities should be made. By providing a visualisation of the distribution of the scores assigned to each piece of software conclusions can be drawn about the expected severity of future vulnerabilities.

## 3.4. Comparisons to Existing Software

Google and Microsoft Header Analysers Both of the tools discussed in Sections 2.3.1 and 2.3.2 produced detailed information on the servers that are being used to send and received messages, with Google's tool also clearly reporting when its own servers were used to send a message. The software should mimic this by providing a similar level of detail on the devices being used to send information, and extend this by looking up information on the device's owning organisation. Additionally, a more exhaustive search of the other fields should be conducted, so more information about the sender can be provided than the immediately available details such as time, sender's e-mail and recipient.

MITRE CVE Lookup and Norton Vulnerability Protection The tools discussed in Sections 2.4.1 and 2.4.2 are both targeted at very different demographics. The MITRE CVE Lookup is designed for IT professionals and system administrators wishing to gather more information about specific vulnerabilities and software, requiring knowledge of the software present on a network or device. The information presented is also not structured or sorted in a clear fashion. Norton's tool, on the other hand, is focused on individual users who administer their own systems. The information is presented in such a way as to warn them as to which software needs updating or patching against a vulnerability, but provides few details on the nature of the vulnerabilities.

The tool that is described in this report ought to be able to bridge the gap between these two tools, providing a useful and relevant list of vulnerabilities, without overloading the information provided, or requiring complex search terms to be crafted.

# 3.5. Typical Use

On starting the application, the user will provide an e-mail that they wish to have analysed. This will then be parsed, and some relevant information presented in a table.

Lastly, an option is available to view the information about security vulnerabilities in a separate webpage, forming the main output of the program.

The resultant webpage will be structured as in Table 1. It will then be possible for the user to click on the representations of the devices to find out more information. It will also be possible to search within the vulnerability list to find more information, as well as filter by impact and availability details.

Email Header Information					
Sender Information (Name, originating domain)  Sender Software (Presented as a list with likely organisation)					
Graphical representation of devices used to deliver the e-mail					
List of derived information including found software and similar information					
Histograms for vulnerability scores, separated by product					
Table of disc	Table of discovered CVEs that can be searched and filtered				

Table 1.: Format of presented data found in e-mail header

# 4. Implementation

#### 4.1. Overview

In order to satisfy the aims of this project, and building on the presented objectives, this chapter discusses the implementation of the software intended to analyse e-mails, starting with the required definitions before presenting the algorithms and data structures that are needed.

#### 4.2. Definitions

The following covers the essential definitions required for the notation and concepts that will be discussed in this document.

#### 4.2.1. Parsing

In order to aid the parsing of the e-mail header, a combination of regular expressions and context-free grammars are needed, and defined as follows.

**Alphabets and Languages** A set of symbols, usually denoted as  $\Sigma$ . A language is a subset of  $\mathcal{P}(\Sigma)$ .

The following special classes are provided as part of the Perl-Compatible Regular Expression library, and are subsets of the alphabet of Unicode characters, defined in PHP Group et al. n.d.

<b>alnum</b> — letters and digits	lower — lower-case letters				
alpha — letters	<pre>print — printing characters (including</pre>				
ascii — the set of ASCII characters (character codes $0-127$ )	spaces)  punct — punctuation marks (printing characters excluding letters and spaces)				
<ul><li>blank — tabs or blank spaces</li><li>cntrl — control characters</li></ul>	space — white space				
digit — decimal digits	<b>upper</b> — upper case letters				
graph — printing characters (excluding	word — "word" characters (same				
spaces)	<b>xdigit</b> — hexadecimal digits				

#### Regular Languages

Regular languages are defined as follows:

- $\emptyset$  and  $\{\epsilon\}$  are regular languages
- for each  $a \in \Sigma$ ,  $\{a\}$  is a regular language
- if A and B are both regular,  $A \cup B$ ,  $A \cdot B$  and  $A^*$  are regular languages.
  - $-A \cup B$  is the union of two languages.  $A \cup B = \{s : s \in A \lor s \in B\}$
  - $-A \cdot B$  is the concatenation of two

languages. 
$$A \cdot B = \{ab : a \in A, b \in B\}$$

 $-A^*$  is the Kleene star of a language.

$$A_0 = \{\epsilon\}$$

$$A_1 = A$$

$$A_{i+1} = \{aa' : a \in A_i, a' \in A\}$$

$$A^* = \bigcup_{i \in \mathbb{N}} A_i$$

#### **Context-Free Grammars**

A context-free grammar G is defined as  $G = (V, \Sigma, R, S)$  where:

 $\bullet$  V is a variable.

- R is a relation defined over  $V \to (V \cup \Sigma)^*$
- $\Sigma$  is the alphabet of symbols.
- $\bullet$  S is the start symbol

For example,  $\langle S \rangle$  is the field name with the associated productions  $\langle T \rangle \langle U \rangle$ , where T and U are productions.

$$\langle S \rangle \models \langle T \rangle \langle U \rangle$$

For example,  $\langle S \rangle$  is the field name with the associated productions  $a \langle U \rangle$ , where a is a terminal symbol.

$$\langle S \rangle \models a \langle U \rangle$$

This is then extended in the following ways used in the RFC syntax.

The square brackets are used to indicate an optional element.

$$\langle \text{field} \rangle \models \langle \text{field-name} \rangle : [\langle \text{field-body} \rangle] \text{ CRLF}$$

The asterisk is used to indicate an element that appears 0 or more times. n\* is used to indicate a component that repeats n or more times.

$$\langle \text{fields} \rangle \models \langle \text{dates} \rangle \langle \text{source} \rangle 1 * \langle \text{destination} \rangle * \langle \text{optional-fields} \rangle$$

The hash-symbol is used to indicate an element that appears a certain number of times. m \* n is used to indicate a component that repeats at least m times and at most n times.

$$\langle \text{fields} \rangle \models \langle \text{dates} \rangle \langle \text{source} \rangle 1 \# \langle \text{destination} \rangle * \langle \text{optional-fields} \rangle$$

The | is used to indicate a selection between a pair of elements.

$$\langle \text{fields} \rangle \models a \mid b$$

#### 4.2.2. Database Queries

The following notations will be used for the CVE database queries.

**Set-Theoretic Operators** The operators  $F \cup G$ ,  $F \cap G$ ,  $F \setminus G$  behave as is expected for these operators, resulting in the union, intersection and difference of the sets. The only proviso being that the attribute names must match.

#### Selection

$$\sigma_{\text{product}=\text{thunderbird}}D$$

The above notation is used to indicate a search over the attribute named "product" for the string "thunderbird" in the database table D. As a single database is only being used, this may be occasionally elided. The output of this function is another object of the same type as D.

#### **Projection**

$$\pi_{\text{product}}D$$

The above notation is used to indicate a projection on the attribute named "product" in the database table D. The output of this function is another object of the same type as D.

**Composition** The above functions results can be composed repeatedly to produce more specific search queries.

#### 4.2.3. Data Structures

These will be drawn using square boxes to represent single objects that are encapsulated within an object. Square boxes with an inner square box indicate some collection of objects.

Thin arrows will be used to denote the encapsulation relation, with thicker arrows being used to list relevant public methods.

Where the type of an object can be expressed simply, the following conventions are used:

**Functions** —  $\alpha \to \beta$  Str is a function from  $\alpha$  to  $\beta$  stored using a Str object in Java.

**Tuples** —  $(\alpha, \beta)$  represents a two-tuple containing objects of type  $\alpha$  and  $\beta$ , respectively. This extends naturally for arbitrarily many objects.

**Lists** —  $[\alpha]$  represents a list or array of objects, all with type  $\alpha$ .

## 4.3. Data Extraction and Parsing

The parser's operation completes in a number of stages, following RFC822 (Crocker 1982). The header is divided up into two disjoint sections, the routing information (Received from...) and the key-value map of other pertinent information.

#### 4.3.1. Received fields

The received fields are the most complicated part of the e-mail header to parse, as they are described by a non-trivial grammar, presented below.

```
\langle \text{message} \rangle \models \langle \text{fields} \rangle * (\text{CRLF} * text)
                              (fields)
                                               \models \langle dates \rangle \langle source \rangle 1 * \langle destination \rangle * \langle optional-fields \rangle
                                \langle \text{field} \rangle \models \langle \text{field-name} \rangle : [\langle \text{field-body} \rangle] \text{ CRLF}
                   (field-name) ⊨ any word consisting of CHAR, excluding CTLs, SPACE, and "":"
                   \langle \text{field-body} \rangle \models \langle \text{field-body-contents} \rangle \text{[CRLF } LWSP\text{-}char \langle \text{field-body} \rangle]
\langle \text{field-body-contents} \rangle \models ASCII characters
                            \langle \text{source} \rangle \models [\langle \text{trace} \rangle] \langle \text{originator} \rangle [\langle \text{resent} \rangle]
                              \langle \text{trace} \rangle \models \langle \text{return} \rangle 1 * \langle \text{received} \rangle
                            \langle \text{return} \rangle \models \text{Return-path: } \langle \text{route-addr} \rangle
                        \langle \text{received} \rangle \models \text{Received}:
                              \langle \text{cont.} \rangle \models [\text{from } \langle \text{domain} \rangle]
                               \langle \text{cont.} \rangle \models [\text{by } \langle \text{domain} \rangle]
                               \langle \text{cont.} \rangle \models [\text{via } \langle \text{atom} \rangle]
                               \langle \text{cont.} \rangle \models *(\text{with } \langle \text{atom} \rangle)
                               \langle \text{cont.} \rangle \models [\text{id } \langle \text{msg-id} \rangle]
                              \langle \text{cont.} \rangle \models [\text{for } \langle \text{addr-spec} \rangle]
                               \langle \text{cont.} \rangle \models ; \langle \text{date-time} \rangle
                           \langle msg-id \rangle \models \langle \langle addr-spec \rangle \rangle
                    \langle addr\text{-spec}\rangle \models \langle local\text{-part}\rangle \otimes \langle domain\rangle
                    \langle local-part \rangle \models \langle word \rangle * (. \langle word \rangle)
                              \langle word \rangle \models \langle atom \rangle \mid \langle quoted\text{-string} \rangle
                         \langle domain \rangle \models \langle sub-domain \rangle * (.\langle sub-domain \rangle)
                \langle \text{sub-domain} \rangle \models \langle \text{domain-ref} \rangle \mid \langle \text{domain-literal} \rangle
                  \langle domain-ref \rangle \models \langle atom \rangle
                    \langle date-time \rangle \models [day,] date time
                              \langle atom \rangle = 1* any character excluding specials, SPACE and CTLs
```

An example field is as follows:

```
Received: from relay12.mail.ox.ac.uk (129.67.1.163)
```

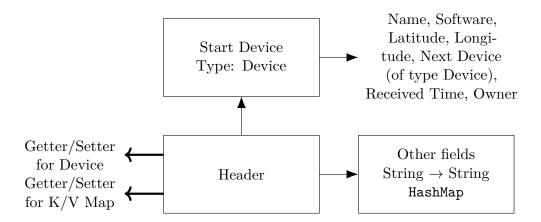

Figure 6.: Header Data Structure Format

```
by HUB05.ad.oak.ox.ac.uk (163.1.154.231) with Microsoft SMTP Server id 14.3.169.1; Sat, 14 Nov 2015 10:55:35 +0000
```

Of particular interest is the pair of hostnames (both are needed as each line is analysed independently, therefore it is not necessary to treat the last line as a special case) and their associated IP addresses. The hostname is of more interest, as performing an IP address lookup is less complicated than determining a hostname. The software used is identified by the with field, and is also of interest, however, is insufficient in most cases to produce meaningful CVE data.

#### 4.3.2. Other fields

These are read by a Python script and output to STDOUT to be read by the Java parser in a consistent format. These are then loaded into a hash-map to allow quick lookup.

#### 4.3.3. Input Data Structures

The raw string of the message header is the only input to this module.

#### 4.3.4. Output Data Structures

The data structure presented in Figure 6 shows the output of the parsing and textual analysis module, which is then provided as an input to the analysis modules.

## 4.4. Analysis

After completing the parsing of the fields, it is then ready to be analysed for different features. All of the analysers implement the HeaderAnalyser interface, requiring information about the header to be analysed, and the currently running application. All of these then implement the Runnable interface, allowing the class to be run asynchronously.

#### 4.4.1. Text-Based

The fields from the header are analysed in different modules, with searches being performed for specific strings. Of particular interest to Oxford Nexus users is the "X-Oxford-Username" string, containing the username of the individual that sent the message. As confirming the username is a fairly standard security procedure for an IT support technician, having access to this information could allow a phisher in a later stage of an attack to increase their credibility.

In some cases, the likely keys that are being searched for are known in advance, and can then be checked against the hash-map of entries.

An example of this approach is for the specific check for an Oxford username, as shown in Algorithm 1.

```
Input: Header

Output: Any username that is found

kws \leftarrow \{X-0xford-Username, X-Username, X-Authenticated-User\};

foreach kw \in kws do

| if kw \in Header.KvMap then
| return Header.KvMap(kw);
| end

end
```

**Algorithm 1:** Lookup based on a known key

Alternatively, we may be interested in properties of the keys, necessitating a search over the keys, as shown in Algorithm 2.

```
Input: Header

Output: Any information relating to Microsoft Exchange that is found foreach Key \ k \in Header.KvMap \ do

if k \ starts\text{-}with \ X\text{-}MS\text{-}Exchange \ then

return Header.KvMap(k);
end
end
```

**Algorithm 2:** Lookup based on a key property

#### 4.4.2. Client Inference

In Nurse et al. 2015, a number of different e-mail clients were identified based on the header tags that were present. By identifying these pieces of software likely to be found on a user's machine, we gain a significant amount of information from them, and should therefore devote some effort to correctly identifying them. Using a number of e-mail samples provided, I have been able to extract examples for a number of different e-mail clients, and use them to infer the client being used. Using a sample of e-mails, it is possible to find information for additional e-mail clients and senders, such as (but not limited to) PHPMailer and Foxmail. A number of these approaches are shown in Algorithm 3.

```
Input: Header
Output: The name of the software that is likely being used, and necessary CVE
         Product name (elided for brevity)
\\Outlook Keywords
\leftarrow {Accept-Language, Content-Language, Threat-Index, Threat-Topic};
if "Message-ID" \in Header.KvMap then
   if Header.KvMap("Message-ID") contains "email.android.com" then
      return "Android Device";
   end
else if "X-Mailer" \in Header.KvMap then
   switch Header.KvMap("X-Mailer") contains do
      case "iPhone"
       return "iPhone"
      end
      case "Outlook Express"
       | return "Microsoft Outlook Express"
   endsw
else if "User-Agent" \in Header.KvMap then
  return "Thunderbird";
else if Header.KvMap \cap OutlookKeywords \neq \emptyset then
   if "X-Mailer" \in Header.KvMap then
   | return Apple Mail
   else
   return Outlook
   end
end
```

Algorithm 3: Client Inference Technique

#### 4.4.3. Database Queries

Using the results gathered from the text-based queries and analysis of the received fields, relevant software configurations are extracted and queried against results in the CVE database. These are then parsed and collated in preparation for displaying the outputs. Specifically, the queries are limited to those matching the product name, and vulnerabilities that can be remotely executed.

As more information is found, more details of products used will also become available. These are added asynchronously.

```
Input: Header product name p
Output: CVE Entries

cve-list \leftarrow \emptyset;

foreach s \in \sigma_{vector \neq LOCAL}\sigma_{product=p}D do

| cve-builder \leftarrow blank cve;
| cve-builder.id \leftarrow \pi_{\text{CVE-ID}}s;
| ... - extract other features;
| cve-list \leftarrow cve-list \cup make(cve-builder);

end

return cve-list;
```

**Algorithm 4:** Extracting CVE entries

#### 4.4.4. Analysis Modules and Data Flow

The following modules are used in the analysis of e-mail headers. Via HeaderAnalyser, they all subclass Callable<Object>, allowing them to return values to calling classes when side-effects are undesirable.

**HeaderAnalyser** — the base interface for all analysis modules.

**ClientInferrer** — as described in Algorithm 3, this analyses the entire header, looking for specific indicators relating to e-mail clients.

**DeviceAnalyser** — Extracts the hostname, and then IP address, or IP address for each device, allowing a lookup of its co-ordinates.

**Exchange Header Analyser** — determines if a Microsoft Exchange server has handled the message.

**GeolPAnalyser** — Given an IP address, this module looks up the latitude and longitude for said IP address. This search will fail for local IP addresses (commonly found in the 192.168.0.0/16 subnet).

**UsernameHeaderAnalyser** — This module searches for the specific X-Oxford-Username field, one of the most common fields in my collection of e-mail headers, as well as a number of more generic username fields.

**SenderInformationExtractor** — This is used to lookup an individual's name from the set of fields, if it is available.

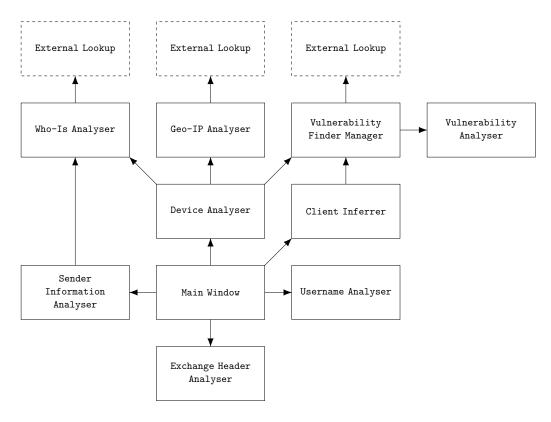

Figure 7.: Information flow between analysis modules

**VulnerabilityAnalyser** — For each entry from the database as a **String**, this analyser returns a **VulnerabilityDisclosure** object.

**VulnerabilityFinderManager** — this is an interface for other classes to implement. A reference implementation is provided in **VulnerabilityFinderManagerImpl**, with a simple implementation found in **NoopVulnerabilityFinderManager** for systems that lack the CVE database.

**WholsAnalyser** — Using a hostname, this looks up the relevant owning organisation for a server, if it is available.

Figure 7 shows the direct interaction of the analysis modules. Unless noted, if an arrow goes from  $\alpha$  to  $\beta$ , it is used to indicate that  $\alpha$  calls  $\beta$ , passing data from  $\alpha$ , and/or receiving data from  $\beta$ .

Where possible, these requests are non-blocking, that is run asynchronously, while waiting for other results to be computed. THe biggest delay is caused by the CVE Database lookup, followed by the WhoIs lookup and then the GeoIP lookup. The CVE database lookups require the most time as they are often consuming large amounts of data, and searching over specific fields. The WhoIs lookup takes place over the network, causing its response time to be unpredictable, however, its relatively small response size reduces the time needed. Finally, the GeoIP lookup takes place locally, with a relatively small response, allowing it to complete quickly.

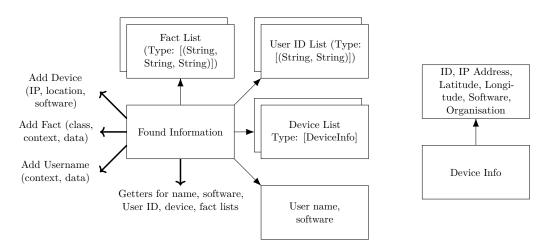

Figure 8.: Found Information Data Structure Format

#### 4.4.5. Output Data Structures

The output of the analysis modules is compiled into the FoundInformation class, which represents the list of facts, servers and other information that has been gathered from an e-mail.

# 4.5. Visualising the Results

Using a pre-existing template, the results from the e-mail analysis will be presented in a temporary webpage, which can then be saved independently. Other than the referenced JavaScript libraries, and a freely available set of country borders, the document requires no additional information or database access, allowing it to be quickly shared.

In order to export the results, the process described in Algorithm 5 are taken. The *keyword* objects referred to are one of a number of specific strings representing one of the sender's name, organisation, client or usernames; CVE entries, fact entries, products that have been found, or servers that have been found.

```
Input: Found Information Object

Output: Webpage

lines \leftarrow read\text{-lines} \text{(webpage-template)};

foreach l \in lines do

| if l contains keyword then
| webpage \leftarrow_+ l \text{[field from FoundInformation/keyword]};

else
| webpage \leftarrow_+ l;
end

end

return webpage;
```

Algorithm 5: Exporting the Found Information to Visualisations

While most of the data processing has been completed by the time the webpage is displayed,

some computational steps are required to render the histograms and map, which are detailed in Algorithm 6

```
Input: Webpage text
Output: Visualisation of Webpage
foreach u \in userentries do find HTML list of usernames and append u;
foreach f \in factentries do find HTML table of facts and append f;
foreach c \in cveentries do
   if c matches search string \vee search string \stackrel{?}{=} \epsilon then
       if \langle c_{impact}, c_{access} \rangle matches filters then
        find HTML table of facts and append f;
       end
   \quad \mathbf{end} \quad
end
foreach c \in cveentries do distributions [c_{software}] \leftarrow_{\cup} c_{score};
foreach d \in distributions do draw histogram for d;
foreach s_i \in servers do project s_i onto map;
foreach s_i \in servers do draw link between s_i and s_{i+1} onto map;
return webpage;
                    Algorithm 6: Rendering the Visualisation
```

# 5. Evaluation

After producing the application described in Chapter 4, referring back to the design specifications to determine its performance against the stated criteria was the next step.

# 5.1. Methodology

Using a sample of e-mails provided by my supervisor, each of them was run through the final version of the program, and scored based on the following attributes:

- Let M be the total number of received fields.
- $\bullet$  Let N be the total number of other fields.
- 1 point is added to the total R for each piece of information found in a Received field for the following:
  - One of device name or IP address
  - Software or protocol used
  - Vulnerabilities found for the relevant piece of software
  - Location Data
- 1 point is addded to F for each piece of information found in other fields.

The final score for an e-mail is given as

$$\frac{1}{2} \left( \frac{R}{4M} + \frac{F}{N} \right)$$

to give a value between 0 and 1 for each e-mail.

The e-mails received have been numbered from 1 up to 70, and a random sample of size 30 was selected using the following code:

```
>>> random.seed()
>>> random.sample(list(range(1,70)), 30)
[64, 48, 11, 21, 63, 68, 27, 69, 29, 8, 28, 34, 13, 57, 10, 3, 22, 32, 23, 49, 26, 45, 19, 1, 36, 46, 41, 18, 20, 17]
```

Thus giving a sorted list of the following e-mails: 1, 3, 8, 10, 11, 13, 17, 18, 19, 20, 21, 22, 23, 26, 27, 28, 29, 32, 34, 36, 41, 45, 46, 48, 49, 57, 63, 64, 68, 69.

# 5.2. Sample Output

The following pages show the results of running the completed software on the e-mail labelled 11.txt, the contents of which is listed in Fragment 5.1. The full table of CVE entries is elided for brevity. The entries in this colour are associated with points scored for R, and the entries in this colour are associated with points scored for F.

Sea	arch Q
CVE- ID	Summary
CVE- 2010- 0266	Microsoft Office Outlook 2002 SP3, 2003 SP3, and 2007 SP1 and SP2 does not properly verify e-mail attachments with a PR_ATTACH_METHOD property value of ATTACH_BY_REFERENCE, which allows user-assisted remote attackers to execute arbitrary code via a crafted message, aka "Microsoft Outlook SMB Attachment Vulnerability."
CVE- 2008- 5424	The MimeOleClearDirtyTree function in InetComm.dll in Microsoft Outlook Express 6.00.2900.5512 does not properly handle (1) multipart/mixed e-mail messages with many MIME parts and possibly (2) e-mail messages with many "Content-type: message/rfc822;" headers, which allows remote attackers to cause a denial of service (infinite loop) via a large e-mail message, a related issue to CVE-2006-1173.
CVE- 2002- 1056	Microsoft Outlook 2000 and 2002, when configured to use Microsoft Word as the email editor, does not block scripts that are used while editing email messages in HTML or Rich Text Format (RTF), which could allow remote attackers to execute arbitrary scripts via an email that the user forwards or replies to.
CVE- 2006- 2057	Argument injection vulnerability in Mozilla Firefox 1.0.6 allows user-assisted remote attackers to modify command line arguments to an invoked mail client via " (double quote) characters in a mailto: scheme handler, as demonstrated by launching Microsoft Outlook with an arbitrary filename as an attachment. NOTE: it is not clear whether this issue is implementation-specific or a problem in the Microsoft API.
CVE- 2007- 2227	The MHTML protocol handler in Microsoft Outlook Express 6 and Windows Mail in Windows Vista does not properly handle Content- Disposition "notifications," which allows remote attackers to obtain sensitive information from other Internet Explorer domains, aka "Content Disposition Parsing Cross Domain Information Disclosure Vulnerability."
CVE- 2005- 1213	Stack-based buffer overflow in the news reader for Microsoft Outlook Express (MSOE.DLL) 5.5 SP2, 6, and 6 SP1 allows remote malicious NNTP servers to execute arbitrary code via a LIST response with a long second field.
CVE- 2010- 0816	Integer overflow in inetcomm.dll in Microsoft Outlook Express 5.5 SP2, 6, and 6 SP1; Windows Live Mail on Windows XP SP2 and SP3, Windows Vista SP1 and SP2, Windows Server 2008 Gold, SP2, and R2, and Windows 7; and Windows Mail on Windows Vista SP1 and SP2, Windows Server 2008 Gold, SP2, and R2, and Windows 7 allows remote e-mail servers and man-in-the-middle attackers to execute arbitrary code via a crafted (1) POP3 or (2) IMAP response, as demonstrated by a certain +OK response on TCP port 110, aka "Outlook Express and Windows Mail Integer Overflow Vulnerability."
CVE- 2002- 2100	Microsoft Outlook 2002 allows remote attackers to embed bypass the file download restrictions for attachments via an HTML email message that uses an IFRAME to reference malicious content.
CVE- 1999- 0519	A NETBIOS/SMB share password is the default, null, or missing.
CVE- 2008- 2143	Unspecified versions of Microsoft Outlook Web Access (OWA) use the Cache-Control: no-cache HTTP directive instead of no-store, which might cause web browsers that follow RFC-2616 to cache sensitive information.
CVE- 2014- 5359	Directory traversal vulnerability in SafeNet Authentication Service (SAS) Outlook Web Access Agent (formerly CRYPTOCard) before 1.03.30109 allows remote attackers to read arbitrary files via a (dot dot) in the GetFile parameter to owa/owa.
CVE- 2008- 4025	Integer overflow in Microsoft Office Word 2000 SP3, 2002 SP3, 2003 SP3, and 2007 Gold and SP1; Outlook 2007 Gold and SP1; Word Viewer 2003 Gold and SP3; Office Compatibility Pack for Word, Excel, and PowerPoint 2007 File Formats Gold and SP1; Office 2004 and 2008 for Mac; and Open XML File Format Converter for Mac allow remote attackers to execute arbitrary code via (1) an RTF file or (2) a rich text e-mail message containing an invalid number of points for a polyline or polygon, which triggers a heap-based buffer overflow, aka "Word RTF Object Parsing Vulnerability."
CVE-	Microsoft Outlook 2002 Connector for IBM Lotus Domino 2.0 allows local users to save passwords and login credentials locally, even

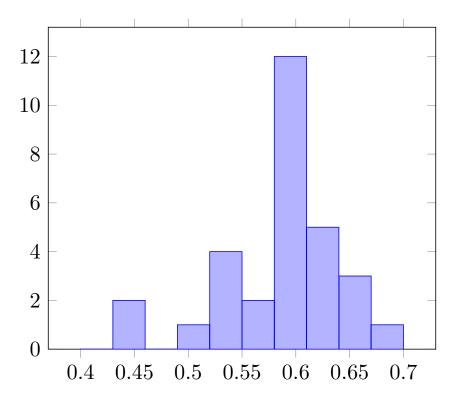

Figure 9.: Distribution of scores from e-mails

# 5.3. Results

Table 2 gives the M and N values for the different sampled e-mails. These were sampled using standard Unix tools: grepping for fields and counting the output. The results for R and F have been listed after completing the testing, after counting the number of entries in the final visualisation.

The final score for the e-mails gives a minimum value of 0.449 and a maximum value of 0.680, with an average of 0.583 and standard deviation of 0.0540. The histogram in Figure 9 shows the distribution of scores from the e-mails, showing a skew towards higher scores. This is a promising result, however, most of the score is contributed to by the trace-fields, with the value of R/4N being consistently around 0.85. As the aim of this project jas both focused on the disclosure of individual's data and of network vulnerabilities, the high score from the trace-fields is a positive result.

During the testing, the following trends were noticed. As many of the e-mails passed through the same set of servers, as they had been received by an Oxford e-mail address, the same set of servers were frequently seen, all of which had associated IP addresses, geolocation data and (except for one server running Microsoft SMTP Server) CVE data for the running software. For an e-mail sent within the University Nexus system, this gives an inflated score, as very few of the servers are missing information.

The score for the information gathered from fields does not take into account the number of fields needed to determine or infer a piece of information. For example, the presence, or absence of multiple fields is required to determine a piece of information. Nor does it consider the relative value of a piece of information, failing to rate the presence of a username

Header	Total Fields	M	N	R	F	$\overline{S}$

Table 2.:  $M,\,N,\,R,\,F$  and score values for chosen headers

above the presence of a particular piece of software also giving false positives.

However, very few e-mails in the testing population contained fields relating to usernames (for example, X-...-User, X-Oxford-Username, X-Authenticated-User) compared to the result in Nurse et al. 2015, which found 14% of e-mails to contain usernames as opposed to the 8% found in the population.

# 6. Conclusions

# 6.1. Summary

As described in Chapter 1, the aim of this project is to support a better understanding of the data that may leaked when e-mails are sent, both from a personal perspective, as well as the corporate data that is leaked concern network configurations and software installations.

To support this, I have developed a tool that can be used to automatically extract information from e-mail headers and analyse its results to display the personal information contained within an e-mail's header, as well as information about the software configurations that may be found on a user's computer, or the servers used to send their e-mail.

This tool has performed well, particularly in extracting data from e-mail headers in connection to the trace-fields with a score of 0.85 for the trace-fields. The lower rate of information that has been extracted from the other fields, while less impressive, is still promising, given that all fields in an e-mail do not necessarily provide information about the sender themself, for example, the subject, CC, and BCC fields.

### 6.2. Future Work

During the late stages of development and testing, a number of missing features quickly became apparent. Due to the limited information available, and the differences in version numbering, a decision was made to search for all available vulnerabilities for an application, allowing the user to discern which were most relevant. Subsequent versions could focus on the different pieces of version data available. For example, esmtp frequently references its version number in the "Received" field frequently.

Alternatively, a better picture may be presented by accumulating multiple e-mails. For example, using the information provided from multiple members of single organisation, a better picture may be built up of the software used by the servers, as well as the network configuration.

The application's response times may also be improved by caching some data in memory, such as WhoIs responses and GeoIP lookups, so that frequently accessed lookups can be completed more quickly.

Additionally, future testing should take place on a larger dataset, using e-mails from a wider variety of sources sent to a number of different recipients.

Finally, it should be possible for an updated version of this application to determine which header fields have been added by mail servers within one's own organisation. For example, e-mail header fields beginning with X-MS-Exchange are seen within almost all e-mail messages sent to recipients within the Oxford domain, adding more false positives to the test results. While it is possible that other preceding e-mail servers have added similar fields, in most cases, these entries yielded little useful data.
